How expressive is finite state linguistics?

$$L(N) := (s \in \{0,1\}^* \mid (\#0\text{'s in } s) \mod N = (\#1\text{'s in } s) \mod N)$$
$$= (s \in \{0,1\}^* \mid \#0\text{'s in } s =_{\mod N} \#1\text{'s in } s)$$

DFA X to accept L(5) must have 5 states

 $x \mod N := remainder after dividing x by N$

$$M \mod +\infty = M$$

 $h \in Ce^{-\alpha} = M$
 $h \in Ce^{-\alpha} = M$
 $h \in Ce^{-\alpha} = M$

DFA to accept L(N) must have N states!

DFA to accept $L(+\infty)$ must have $+\infty$ states! ? But what is $L(+\infty)$?

$$L(+\infty) := (s \in \{0,1\}^* \mid \#0\text{'s in } s =_{mod + \infty} \#1\text{'s in } s)$$
$$= (s \in \{0,1\}^* \mid \#0\text{'s in } s = \#1\text{'s in } s)$$

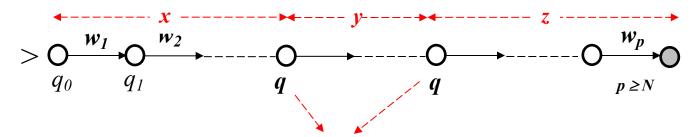

The previous slide is an example of a simple language that is **intuitively** shown to be **unacceptable** by a finite state automaton!

We make this intuition mathematically precise by the **Pumping Lemma**

Consider a DFA X with N states that accepts a language L

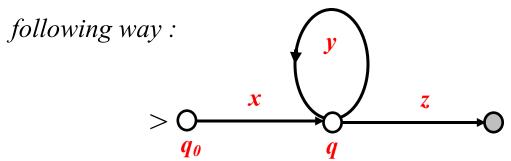

Let $w \in L$ with the property that $|w| \ge N$

Apply w to X starting at the initial state and plot the state transitions as follows:

since the no. of states visited before the arrival at the final state is > N; some state, say \mathbf{q} , is repeated on the way. We assume that \mathbf{q} is the first instance of a state repeating a past instance of itself; hence the states before the second \mathbf{q} are visited are all distinct and are $\leq N$).

The string moving through the states in the previous slide can be plotted in the

Hence: w = x.y.z

where : (i) $|\mathbf{x}.\mathbf{y}| \leq N$ (by the assumption that \mathbf{q} is the first instance of a state repetition);

(ii) |y| > 0 (at least one transition from q to q)

Finally we make the key observation: we can loop from **q** to **q** as many times (including 0 times!) as we want and still end up at the accepting final state!

Hence we conclude that $x \cdot y^j \cdot z$ is accepted by X for all j = 0, 1, 2, ...

Pumping Lemma

Let **L** be a language accepted by a DFA **X** with **N** states.

Let $w \in L$ with $|w| \ge N$.

Then there exists strings x,y and z such that w can be decomposed as:

w = x.y.z where (i) $|x.y| \le N$ and; (ii) |y| > 0.

The DFA X that accepts w must necessarily accept an infinite

collection of strings given by:

 $x.y^j.z \in L$ for all j=0,1,2,...

Pumping Lemma can be used to prove that a language L is not regular;

Or equivalently that L cannot be accepted by a DFA

Caution (dikkat!):Pumping Lemma CANNOT be used to prove that a language

is regular: don't try!! Pumping Lemma shows that a given language L is not regular by contradiction as explained by the following steps:

Step 1. Assume that L is accepted by some DFA with N states (to be contradicted at the end!).

Step 2. Choose a specific and suitable (simple?) w in L with $|w| \ge N$.

Step 3. Using the decomposition w = x.y.z and the facts $|x.y| \le N$ and |y| > 0, express x,y and z according to your choice of w.

Step 4. Show that according to x,y and z as computed in **Step 3** the string x,y j z is **NOT** in **L** for some $j \ge 0$ (usually j=0) contradicting the Pumping Lemma .

5

Proving languages non-regular!

Example 1

 $L = (s \in \{0,1\}^* \mid \#0$'s in s = #1's in s) is non-regular!

Assume the contrary (L is regular!) and apply the steps in the previous slide

Step 1 Let N be the no. of states of a DFA that accepts L

Step 2 Choose $w = 0^N 1^N$ which is in L; then $|w| = 2N \ge N$ as demanded by the PL.

Step 3 Then $w = 0^N 1^N = x.y.z$, where $|x.y| \le N$ and |y| > 0

Hence $x.y=0^p$; $y=0^q$, and thus $x=0^{p-q}$ where $p \le N$, q>0 and so $z=0^{N-p}$. 1^N

Step 4 But according to **PL** $x.y^j.z \in L$ for all j=0,1,...; and for j=0 this implies that

 $x.z \in L$. Yet this cannot be true since for q > 0, $x.z = 0^{p-q}$. $(0^{N-p}. 1^N) = 0^{N-q}.1^N \not\in L$

Example 2

 $L = (s \in \{0,1\}^* \mid s = u.u, u \in \{0,1\}^*)$ is non-regular!

Step 1 Let N be the no. of states of a DFA that accepts L

Step 2 Choose $w = 0^N.1.0^N.1 = u.u$ with $u = 0^N.1$; then $w \in L$ and $|w| = 2N + 2 \ge N$.

Step 3 Then since $w = 0^N \cdot 1 \cdot 0^N \cdot 1 = x \cdot y \cdot z$, where $|x \cdot y| \le N$ and |y| > 0 it follows that

 $x.y = 0^p$, $y=0^q$ with $p \le N$, q > 0 and so $x = 0^{p-q}$; $z = 0^{N-p} \cdot 1.0^N \cdot 1$

Therefore $x.z = 0^{p-q}.0^{N-p}.1.0^{N}.1 = 0^{N-q}.1.0^{N}.1$

Step 4 According to the PL for j=0, we must have $x,z \in L$.

But if $x.z \in L$ there are two cases for obtaining xz = u.u corresponding to cutting the dividing point among the first or second group of zeros, and both cases lead to the impossibility of such a division to yield $xz = 0^{N-q}.1.0^{N}.1 = u.u$

Hence $x.z \notin L$, a contradiction! and thus L cannot be a regular language.

Example 3

 $L = (s \in I^* | s = I^k, k \text{ a prime number}) \text{ is non-regular!}$ add q to both sides

Step 1 Let N be the no. of states of a DFA that accepts L

Step 2 Choose $w = 1^m$ where m is a prime number with m > N+1.

Step 3 $w = 1^m = x.y.z$, where $|x.y| \le N$ and $|y| \ge 0$

Setting r:=|x|, p:=|y| and q:=|z| it follows that m=|x.y.z|=r+p+q, $r+p\leq N$, p>0

Step 4 But according to **PL** $x.y.z \in L$; or r+p.j+q must be a prime number for all integers j. Choosing j:=r+q it follows that r+p.j+q=(r+q).(p+1) must be a prime number! But $r+p \le N$ implies $m \le N+q$ and since by choice m > N+1 we have: $N+1 < m \le N+q$ and therefore $q \ge 2$ and thus $r+q \ge 2$; and since $p+1 \ge 2$ it follows that r+p.j+q=(r+q).(p+1) cannot be a prime number for j=r+q, a contradiction!

8

Closure Properties of Regular Languages

- (1) L,M regular implies (i) $L \cup M$, (ii) L. M and (iii) L* are regular follows from the definition of REs E+E E+E E*
- (2) L regular implies L^c (complement of L) is regular replace the final state set F of a DFA that accepts L by Q F; the resulting automaton accepts L^c
- (3) L, M regular implies $L \cap M$ is regular
- short path : $L \cap M = (L^c \cup M^c)^c$, which by (1) and (2) proves the result
- long path : If A and B are DFA that accept L and M then $A \times B$ is a DFA that accepts $L \cap M$

The Product Automaton A × B

$$A = (Q, \Sigma, \delta_A, s, F_A); B = (R, \Sigma, \delta_B, t, F_B)$$

$$A \times B := (Q \times R, \Sigma, \delta, (s,t), F_A \times F_B)$$
 where

$$\delta((q,r), \sigma) := (\delta_A(q,\sigma), \delta_B(r,\sigma))$$

Fact to be proved by induction on the length of **u**:

$$\delta E((q,r),u) = (\delta_A E(q,u), \delta_B E(r,u))$$

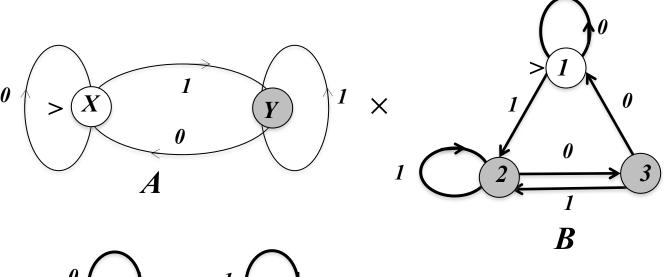

Proof of $L(AxB) = L(A) \cap L(B)$

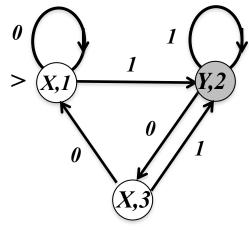

$$u \in L(A \times B) \Leftrightarrow \delta E((s,t),u) \in F_A \times F_B \Leftrightarrow (\delta_A E(s,u), \delta_B E(t,u)) \in F_A \times F_B$$

$$\Leftrightarrow \delta_A E(s,u) \in F_A \wedge \delta_B E(t,u) \in F_B$$

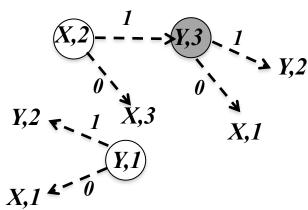

$$\Leftrightarrow u \in L(A) \land u \in L(B) \Leftrightarrow u \in L(A) \cap L(B)$$

Example for the Product Automaton $\mathbf{A} \times \mathbf{B}$

$$A \times B$$

A×B non-reachable part

- (4) L, M regular then L M is regular; $L M = L \cap M$ chence by previous results regularity follows.
- (5) L regular then $L^R := (u \in \Sigma^* \mid u^R \in L)$ where R denotes reversal of strings replace the DFA that accepts L by the NFA obtained from the former by : (i) interchanging initial and final state sets $\,$; and (ii) changing the

CS 302 Spring 2021

direction of all transition arcs.

Decision Problems for Regular Languages

Adjacency $\mathbf{n} \times \mathbf{n}$ matrix \mathbf{A} for a directed graph with \mathbf{n} nodes

 $a_{ij} = 1$ if there is an arc from node i to node j

= 0 otherwise

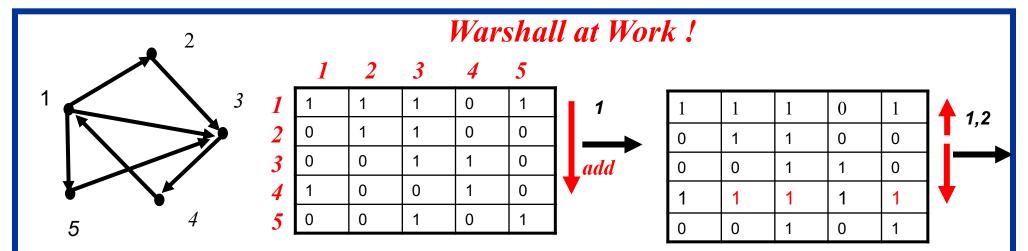

The i-to-j reachability problem: is there a path from node i to node j?

Let $w_{ij}^k = 1$, if there is a path from i to j using intermediate

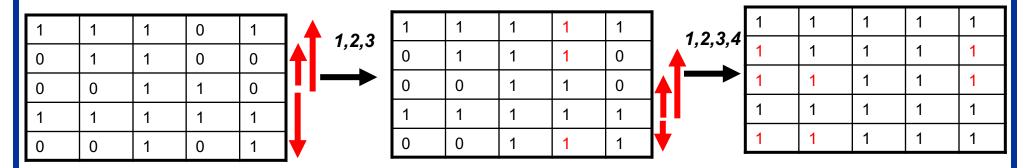

nodes 1, ..., k and = 0 otherwise. Answer to the reachability problem is **YES** iff

 $w^{n}_{ij} = 1$. Note that $[w^{0}_{ij}] = [a_{ij}]$

Warshall's Algorithm: $w_{ij}^{k} = w_{ij}^{k-1} \vee (w_{ik}^{k-1} \wedge w_{ik}^{k-1}), k = 1,...,n$

If new entry node is i then add row i to row $j\neq i$ for which $(ji)^{th}$ entry is 1

Big O functions

Let f(n) be a positive increasing function of the positive integer n.

A function g(n) is called a **big** O function of f(n) shown by g(n) = O(f(n)) iff:

there are constants K_1 , $K_2 > 0$ such that:

 $|g(n)| < K_1 f(n)$, for all $n > K_2$ (g(n) increases no faster than f(n) asymptotically!)

Example

The function $g(n) = n^3 + 3n^2 + 7n + 5 \log(n)$ is an $O(n^3)$ function

$$|g(n)| = n^3 (1 + 3/n + 7/n^2 + 5 \log(n)/n^3)$$

Since for n > 1 we have $1 + 3/n + 7/n^2 + 5 \log(n)/n^3 < (1 + 3 + 7 + 5) = 16$

it follows using log(n) < n for n > 1 that : $|g(n)| < n^3 (1 + 3 + 7 + 5) = 16 n^3$

and therefore result follows with $K_1 = 16$ and $K_2 = 1$

Complexity of Warshall's Algorithm: $w_{ij} = w_{ij} \vee (w_{ij} \wedge w_{ij} \wedge$

Two basic binary operations ('v' and ' \wedge ') for each **i,j** and for k=1,...,n; hence total $2 \times n^2 \times n = O(n^3)$ operations

Notation: for a Finite State Automaton (**DFA** or **NFA**) let A_{σ} denote the adjacency matrix corresponding to the directed graph after removing all transition arcs that are NOT labeled by σ

Solution of the EPSILON-closure algorithm

- (1) Apply Warshall's Algorithm to A_{ε} to compute $W_{\varepsilon} = [w_{ij}] \rightarrow O(n^3)$
- (2) Epsilon closure of state (node) i are the states (nodes) with value 1 in row i of W_{ε}
- (3) Epsilon closure of a set S of nodes are the nodes with value I of the row obtained from the union (' \vee ' = mod 2 addition) of the rows corresponding to the nodes in $S \rightarrow O(n^2)$

hence total complexity is $O(n^3) + O(n^2) = O(n^3)$

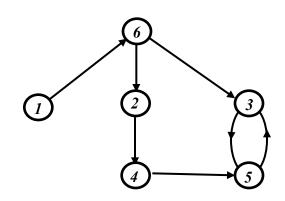

Reachability from a given set of source nodes! Reachability Algorithm

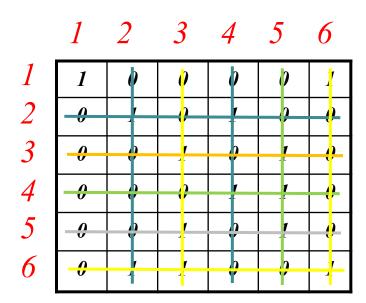

- (1) **Initialization**: Let the initial **LIST** consist of the row indices corresponding to the source nodes.
- (2) Process the current (unused) index in the **LIST** and mark the columns with a **1** at the row corresponding to the current index and; add those column indices that are not already in the **LIST** to the **LIST**.
- (3) Delete the row used and the marked columns and repeat (2) for the **next** (row) index in the **LIST**; stop when all the indices in the **LIST** are used at step (2)!

The vertices reached are members of the final LIST!

At step 2 the maximum no. of columns marked is n; max. total no. of iterations is n

Hence complexity = $O(n^2)$

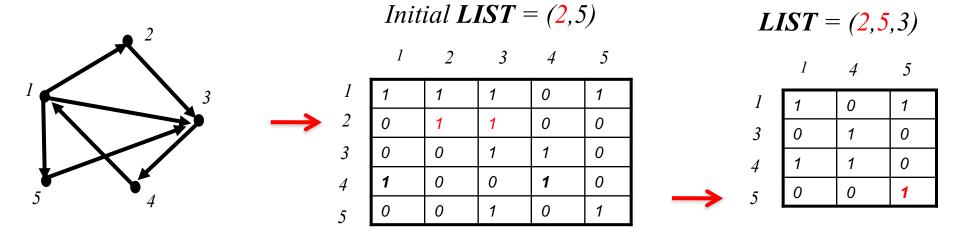

Reachability from vertices 2 and 6

Hence reachable nodes from vertices 2 and 6 is 2,6,4,3,5

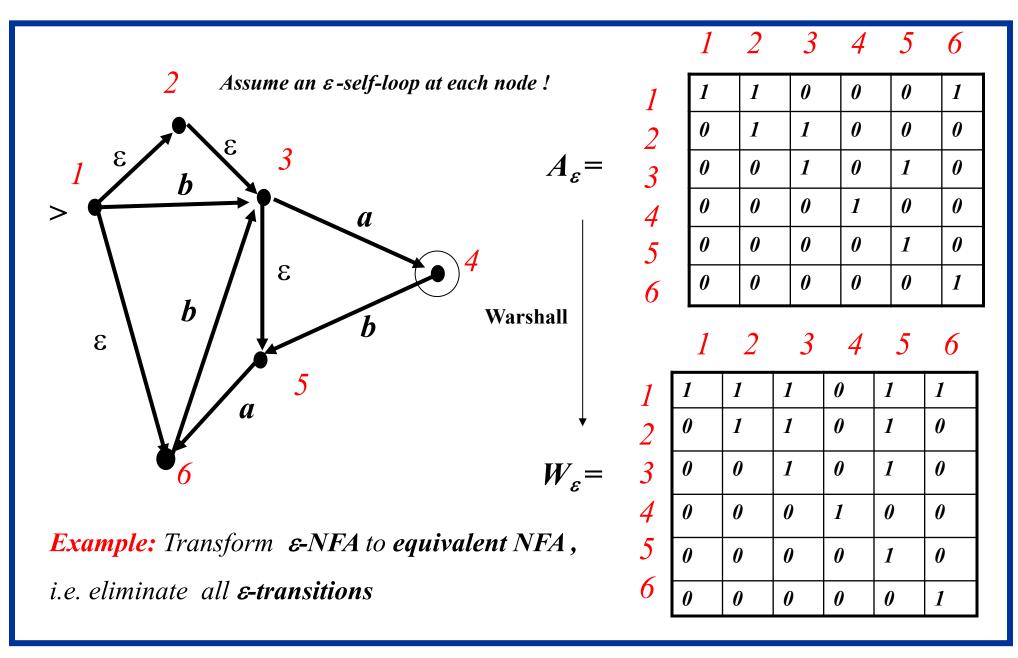

Example: Reachability from vertices 2 and 5

$$LIST = (2,5,3) \qquad LIST = (2,5,3,4) \qquad LIST = (2,5,3,4,1)$$

$$\downarrow 1 \qquad \downarrow 1 \qquad \downarrow$$

reachability from vertices 2,5 = all the vertices

Non &-NFA

Complexity of Regular Language Conversions

initial epsilon-transitions and 2- add rows of Warshall for post- σ epsilon transitions

!- Add rows of A_{σ} according to

(1) ε -NFA to NFA \to First compute $W_{\varepsilon} \to O(n^3)$

For each state and input: $O(n^2)+O(n^2)=O(n^2)$

Hence total effort = $n.|\Sigma|.O(n^2)+O(n^3) = O(|\Sigma|.n^3)$

(2) NFA to DFA $\rightarrow O(n^2)$. $|\Sigma| \cdot 2^n = 2^{(n + \log(O(n^{**2}) \cdot |\Sigma|))} = 2^{O(n)}$

(Exponential!)

complexity of RE
= length of RE

(3) RE to ε -NFA \rightarrow O(n) (n=# basic operations in RE)

(4) **DFA** to **RE**
$$\rightarrow$$
 $O(|\Sigma| \cdot n^2 \cdot 4^n) = 2^{O(n)}$

 $R_{ij}^{k} = R_{ij}^{k-1} + R_{ik}^{k-1}$. $(R_{kk}^{k-1})^{*}$. R_{kj}^{k-1}

(Exponential!)

 $|R_{ij}^{0}| \rightarrow O(|\Sigma|); R_{ij}^{1} \rightarrow 4*O(|\Sigma|)$

$$|R_{ij}^{k}| \rightarrow 4^* |R_{ij}^{k-1}|$$

Testing emptiness of (and membership in) a language L

(1) Emptiness Problem: Is the language accepted by a DFA or an NFA empty?

Apply Reachability Algorithm to NFA (or DFA) where all edges are included disregarding the label. If a final state is reached from any initial state, L is non-empty. Complexity is $O(n^2)$ both for NFA and DFA

For **RE** complexity is **O(n)**

___→ at each step

(2) Membership Problem: does a DFA or an NFA accept the string w?

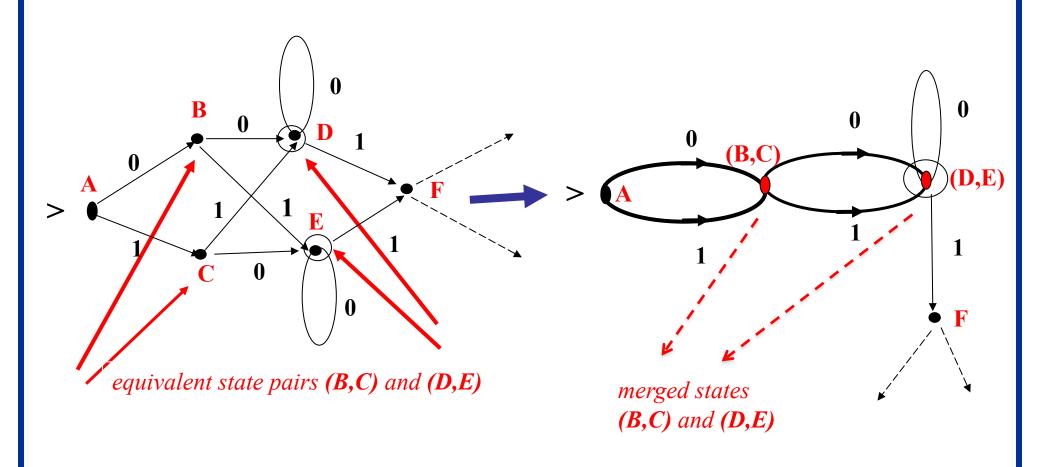

O(|w|+n) for DFA representation.

Warshall

 $O(|w|.n^2+n^2) = O(|w|.n^2)$ for NFA and $O(|w|.n^2+n^3+n^2) = O(|w|.n^2+n^3)$ for ε -NFA representations respectively.

 $O(|w| \cdot n^2 + n^3)$ for **RE** representations.

An informal description of State Equivalence

24

State Equivalence for DFA

 $A = (Q, \Sigma, \delta, s, F)$ be a DFA accepting the language L(A)

q≡q identity
 q≡r ⇔ r≡q commutativity
 q≡t ∧ t≡r ⇒ q≡r transitivity

Definition $q, r \in Q$ are said to be **equivalent** states of A, shown by $q \equiv r$, if **for all** inputs $w \in \Sigma^* : \delta E(q, w) \in F$ **iff** $\delta E(r, w) \in F$

States that are NOT equivalent are called distinguishable

Exercise: Show!

More precisely $q, r \in Q$ are said to be **distinguishable** states of A if **there exists** an input $w \in \Sigma^*$: $\delta E(q,w) \in F$ and $\delta E(r,w) \notin F$

Definition $q, r \in Q$ are said to be k-equivalent states of A, shown by $q \equiv_k r$, if for all inputs $w \in \Sigma^*$ with $|w| \le k : \delta E(q, w) \in F$ iff $\delta E(r, w) \in F$ Note that if $q, r \in Q$ are NOT a k-equivalent pair of states they are NOT equivalent; moreover there is an input w with $|w| \le k$ such that $\delta E(q, w) \in F$ and $\delta E(r, w) \notin F$ That is: they can be distinguished by an input of length no more than k!

26

Theorem Given two states q and r of a DFA and $k \ge 1 : q = r \iff$

for any $\sigma \in \Sigma$, $\delta(q,\sigma) \equiv_{k-1} \delta(r,\sigma)$

Proof of Theorem : \leftarrow (if)

For any w with $|w| \le k$ write it as $w = \sigma . u$ where $|u| \le k-1$.

Then $\delta E(q, \sigma.u) = \delta E(\delta(q, \sigma), u)$ and $\delta E(r, \sigma.u) = \delta E(\delta(r, \sigma), u)$

and since $\delta(q,\sigma) \equiv_{k-1} \delta(r,\sigma)$: $\delta E(\delta(q,\sigma),u) \in F \text{ iff } \delta E(\delta(r,\sigma),u) \in F$

hence $\delta E(q, w) \in F$ iff $\delta E(r, w) \in F$ where $w = \sigma . u$; so q = r

\Rightarrow (only if)

For any u and σ with $|u| \le k-1$ set $w := \sigma.u$ so that $|w| \le k$ Then by assumption $\delta E(q, w) \in F$ iff $\delta E(r, w) \in F$ which implies $\delta E(\delta(q, \sigma), u) \in F$ iff $\delta E(\delta(r, \sigma), u) \in F$ and so $\delta(q, \sigma) \equiv_{k-1} \delta(r, \sigma)$

Recursive computation of distinguishable state pairs

(Table Filling Algorithm)

Basis: A pair (**r,q**) is distinguished by a string of **0** length if one is **accepting** (final) and the other is a **non-accepting** (non-final) state.

Induction: If for some $a \in \Sigma$, $r' = \delta(r, a)$ and $q' = \delta(q, a)$ and r' and q' are distinguishable then r and q are also distinguishable.

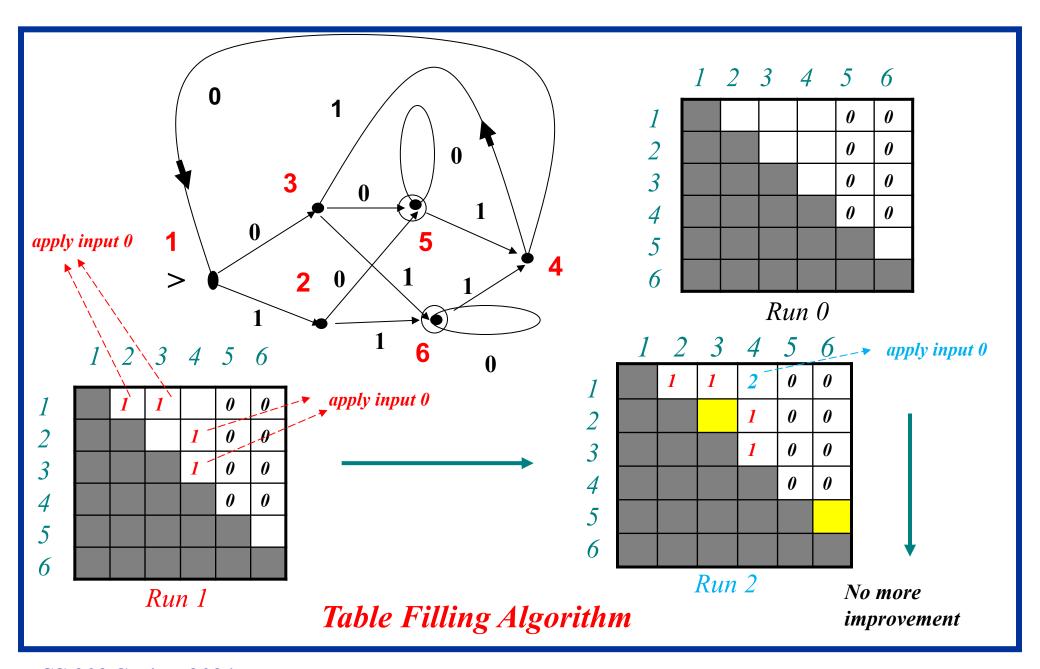

Proof: Given that \mathbf{r} ' and \mathbf{q} ' are distinguishable (i.e. NOT equivalent), there exists an input string \mathbf{u} such that $\delta E(\mathbf{r}', \mathbf{u}) \in F$ and $\delta E(\mathbf{q}', \mathbf{u}) \notin F$ (or vice-versa);

But since (see **Theorem** above) $\mathbf{r'} = \delta(\mathbf{r}, \mathbf{a})$ and $\mathbf{q'} = \delta(\mathbf{q}, \mathbf{a})$ we have

 $\delta E(r',u) = \delta E(\delta(r,a),u) = \delta E(r,a.u) \text{ and } \delta E(q',u) = \delta E(\delta(q,a),u) = \delta E(q,a.u)$

 $\delta E(r, a.u) \in F$ and $\delta E(q, a.u) \notin F$ and therefore r and q are distinguished by the input string a.u

28

CS 302 Spring 2021 29

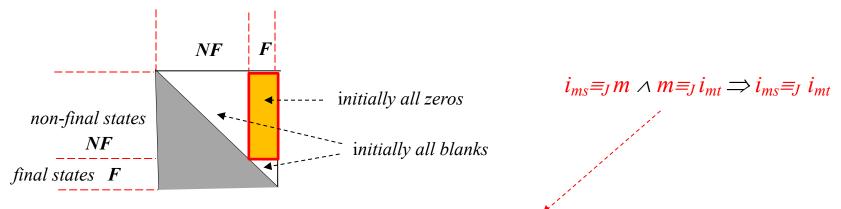

Interpretation of the Table Filling Algorithm

The table starts with squares $\{i,j\}$ marked with a 0 where states $i \in Q$ -F and $j \in F$ or vice-versa. This corresponds to $Run\ 0$ where marked squares correspond to state pairs that are distinguished with the input of zero length, namely the empty string e.

The unmarked squares correspond to state pairs that are **0-equivalent**.

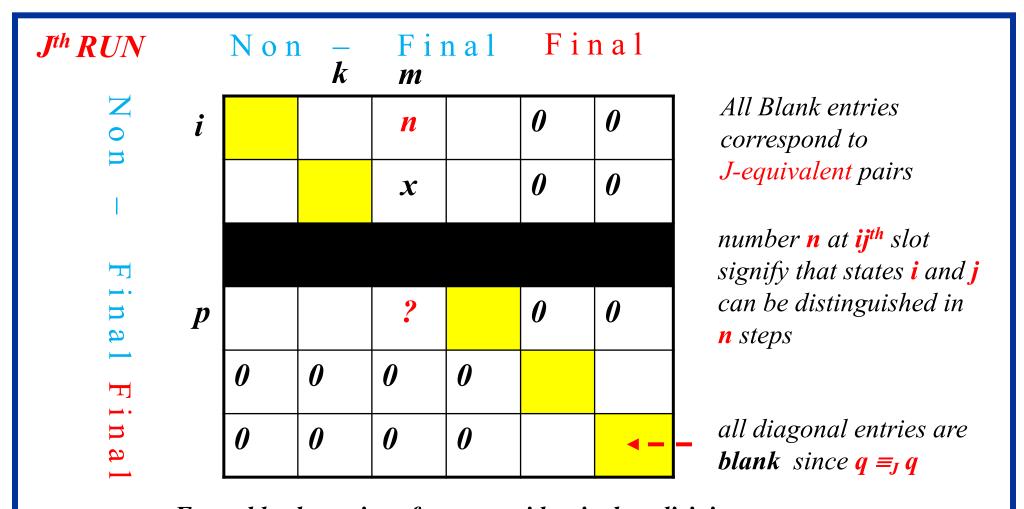

The next run, Run 1, searches for all unmarked state pairs {k,m} that can be moved to a marked state pair {i, j} of Run 0 by some input. If this is possible for some input, then the unmarked pair {k,m} is marked with a 1 implying that the pair {k,m} is distinguishable by an input of length 1. The pairs that remain unmarked in Run 1 are clearly 1-equivalent states. Generalizing: if at Run J an input is found that drives a blank square pair {k,m} to a marked square of Run J-1 then it is marked with the integer J showing that pair {k,m} is distinguishable by an input of length J. Clearly squares that remain blank at Run J correspond to J-equivalent pairs

Interpretation of the Table Filling Algorithm (Cont')

- 1- If at $Run\ J$ the corresponding columns i_{m1} , i_{m2} , ..., i_{mk} at row m are blank then all the $state\ pairs$ in the set $\{m,i_{m1},i_{m2},...,i_{mk}\}$ are J-equivalent.
- 2- For two rows m and p the sets $\{m, i_{m1}, i_{m2}, ..., i_{mk}\}$ and $\{p, i_{p1}, i_{p2}, ..., i_{pl}\}$ are either disjoint; or restricted to blanks they are identical if the darkened regions of the table are also included.
- 3- The maximum value for the number of **runs** before the algorithm halts is no more than K-1 where K = the total number of states.

CS 302 Spring 2021

Fact: blank entries of rows are identical or disjoint

Suppose ik and pk are both blank yet im non-blank and pm blank \rightarrow not possible! $i \equiv_J p$ and $p \equiv_J m$ but $\neg (i \equiv_J m)$ violates transitivity!

CS 302 Spring 2021 32

Interpretation of the Table Filling Algorithm (Cont')

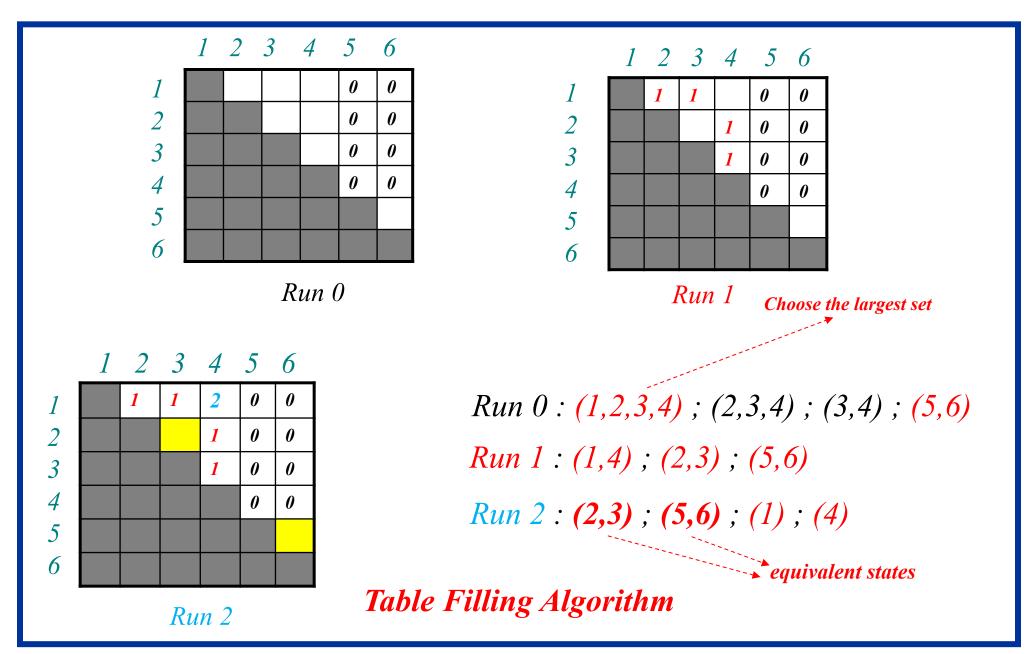

1- Justification of statement 2

2- For two rows m and p the sets $\{m,i_{m1},i_{m2},...,i_{mk}\}$ and $\{p,i_{p1},i_{p2},...,i_{pl}\}$ are either **disjoint**; or restricted to blanks they are identical if the darkened regions of the table are also included.

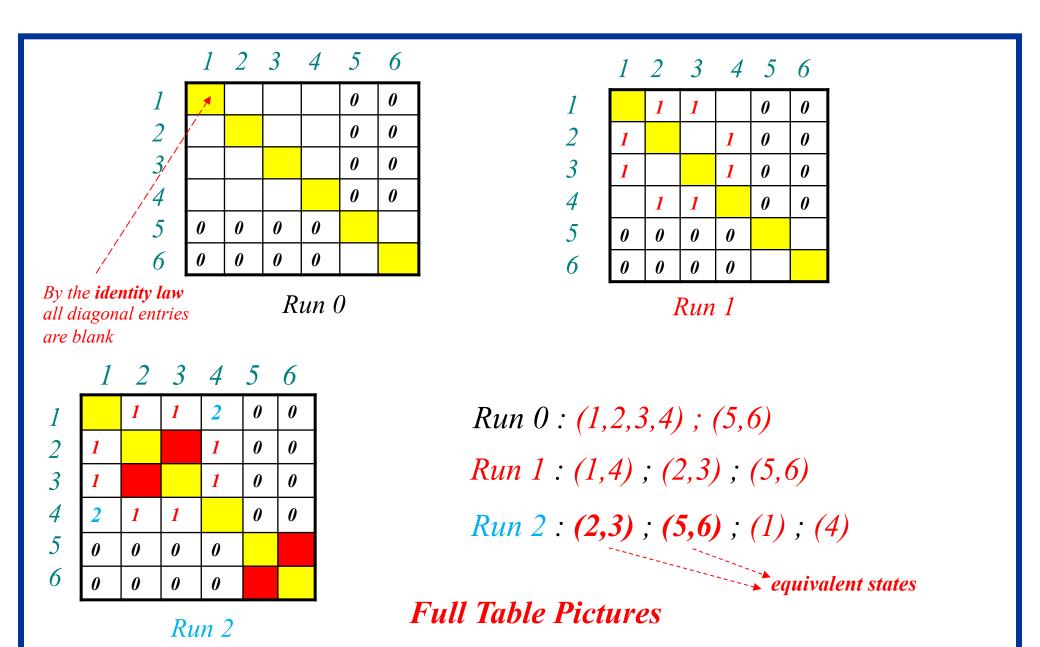

Fact: Suppose that $R_1 = \{m, i_{m1}, i_{m2}, ..., i_{mk}\}$ and $R_2 = \{p, i_{p1}, i_{p2}, ..., i_{pl}\}$ are two row sets of the table which are **not** disjoint.

Then R_1 and R_2 possess a common element x, which implies that **all** the blank entries of the rows m and k (including those in the darkened region) are identical and are **J-equivalent** to x. Finally at each run the state set is partitioned into a disjoint union of state sets some of which (those that are only equivalent to themselves) are singletones; and at each run at least one blank square is filled and hence at least one set is splitted. Since the total number of splittings cannot exceed the total no.of states **-1**, it follows that total number of runs is smaller than K-1.

CS 302 Spring 2021 3.

CS 302 Spring 2021 34

Complexity of the Table Filling Algorithm

Number of entries of the table = $n(n-1)/2 = O(n^2)$

In **each run** and for **every** entry of the table inputs are searched whether a pair is already marked in the previous run. Call this **one** unit of computation. Since the table has $O(n^2)$ number of entries the complexity involved is $O(|\Sigma| n^2)$ for each run.

But because total no. of of runs is at most n-1, which is O(n), at most n

Run 0 = 2 pieces; Run $1 \ge 3$ pieces... Run $J \ge J+2$ pieces

CS 302 Spring 2021 3

Definition

Let $A=(P,\Sigma, \delta_A, s, F_A)$ and $B=(Q,\Sigma,\delta_B, t, F_B)$ be two given **DFA**s.

Two states $p \in P$ and $q \in Q$ are said to be equivalent (shown $p \equiv q$) iff

$$\delta_A E(p, u) \in F_A \text{ if and only if } (\Leftrightarrow) \delta_B E(q, u) \in F_B \quad \forall u \in \Sigma^*.$$

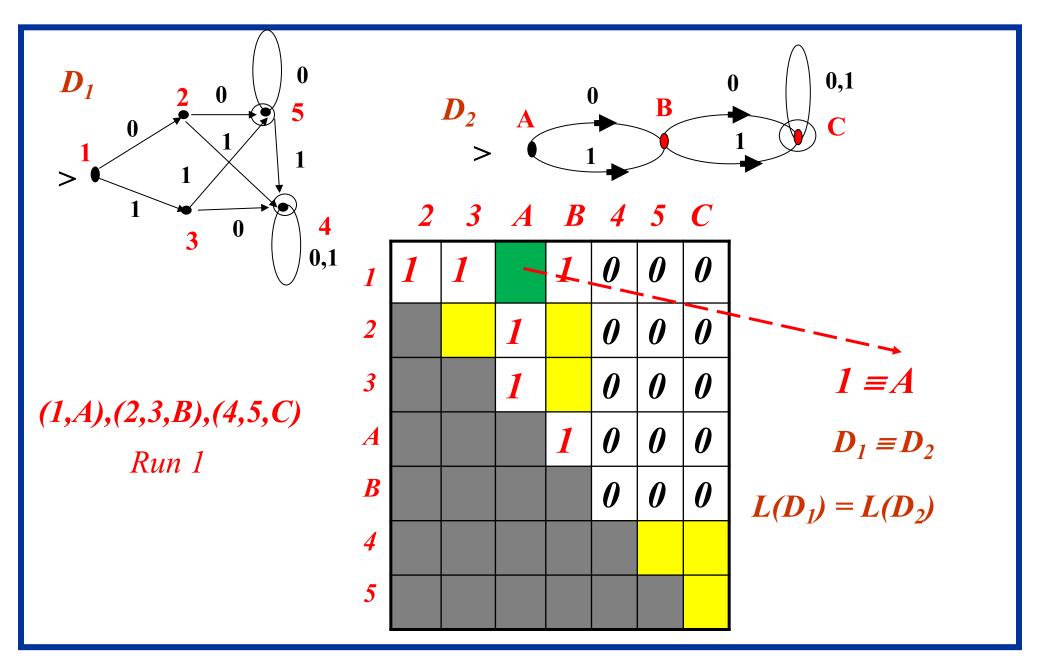

A is said to be equivalent to B (shown $A \equiv B$) iff $s \equiv t$.

Corollary to the Definition

 $A \equiv B$ if and only if L(A) = L(B)

Proof of Corollary

$$A \equiv B \iff s \equiv t \iff \delta_A E(s, u) \in F_A \iff \delta_B E(t, u) \in F_B$$
$$\iff u \in L(A) \iff u \in L(B)$$

CS 302 Spring 2021 38

Theorem

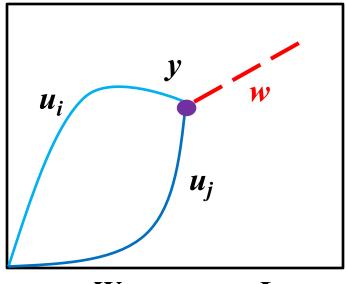

Any pair of states that are not eventually filled by the **Table Filling Algorithm** are equivalent states (either within a **DFA** or in two distinct **DFA**s)

Proof: Call a pair (p,q) unfilled by Algo. a **bad** pair; i.e. there is a shortest distinguishing input string s such that $\delta E(p,s) \in F$ and $\delta_A E(q,s) \notin F$ although Algo. terminated with (p,q) a blank square! Let $s = a_1 . a_2 ... a_J$ and since it is the **shortest** distinguishing sequence for the (p,q) pair it follows that at Run J-1 the (p,q) slot was a **blank** and a_J was the input that moved the (p,q) pair to a marked entry of Run J-1 and thus make s a distinguishing sequence. Hence (p,q) at Run J is marked.

CS 302 Spring 2021 39

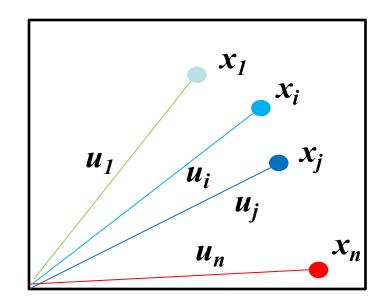

A minimum state machine is obtained after all equivalent states are merged into common states thereby reducing the total number of states. Merging of equivalent states is justified by the proved fact that all the states on a common path from two equivalent states remain equivalent Can you beat a minimum state machine M that accepts L? Suppose you can! then there is an L-accepting DFA, say W, with less states than that of M. Let $u_1, ..., u_n$ be strings that drive the initial state to the n distinct states of M. Apply these input strings to W and by pigeon hole at least 2 such strings will end up in an identical state: a contradiction! Why?

Illustration of 'Can you beat a minimum state machine M that accepts L?'

 $W = accepts L_M$

#states of W < #states of M

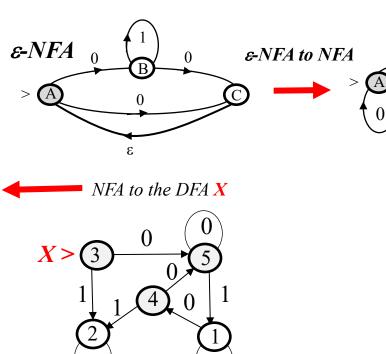

M = minimal state machine

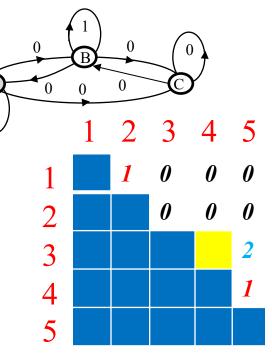

Apply $s = u_i . w$ and $t = u_j . w$ to both Conclusion: $x_i = x_j$

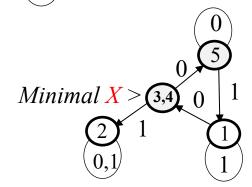

Example

$$E = (0.1 *.0 + 0) *$$

AC	1	Ø

The Abstract Theory

Let Σ be an alphabet and $L \subseteq \Sigma^*$ be a language

For $u,v \in \Sigma^*$: define $u \equiv v$ if $(u.s \in L \Leftrightarrow v.s \in L) \forall s \in \Sigma^*$

[u]:= $\{w \in \Sigma^* \mid w \equiv u\}$ is called an equivalence class with u a representative

L is called regular iff there are a finite number of equivalence classes.

Define (abstractly!) a **DFA** *M* as follows:

 $Q = set \ of \ equivalence \ classes \ ; \ \delta([u],a) := [u.a] \ ; \ s = [e] = initial \ state$

 $F = ([u] \in Q \mid u \in L)$

Every minimum state DFA that accepts L is isomorphic to M

(Myhill-Nerode theory)

Example 1 States as language equivalence classes A D

$$A \quad D \quad B \quad C$$

Minimal state DFA

$$[e] = e \text{ for } A = L_A$$
sets of strings terminating at states A, B, C and D

$$[0] = 0.(0+1)*for B = L_B$$

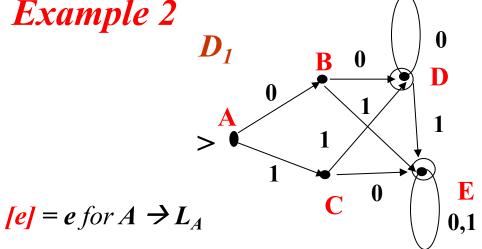

[1] =
$$1.1*(0.0*.1.1*)* = 1*(0*.1*)* for C = L_C$$

$$[1.0] = 1 + (0 + .1 +) *.0 + for D = L_D$$

 L_A , L_B , L_C , L_D are all **disjoint** sets (languages) Why?

$$L = [0] + [1] = L_B + L_C$$

Example 2

 $B \equiv C$ and $D \equiv E$

strings terminating at
$$B = 0 = L_B$$

strings terminating at
$$C = 1 = L_C$$

strings terminating at
$$D = 0.0.0*+1.1.0* = L_D$$

strings terminating at
$$E = 1.0.(1+0)* + 0.1.(1+0)* + (0.0.0*+1.1.0*).1.(1+0)* = L_E$$

$$[0] = [1] = L_B + L_C$$
; $[0.0] = [1.1] = [0.1] = [1.0] = L_D + L_E$

$$L_A$$
, L_B+L_C and L_D+L_E are disjoint languages
